D01 Where is uncertainty continuity documented?

Computed distribution of 23 paper–context assessments from 20 publications. Ribbon width = assessment count.

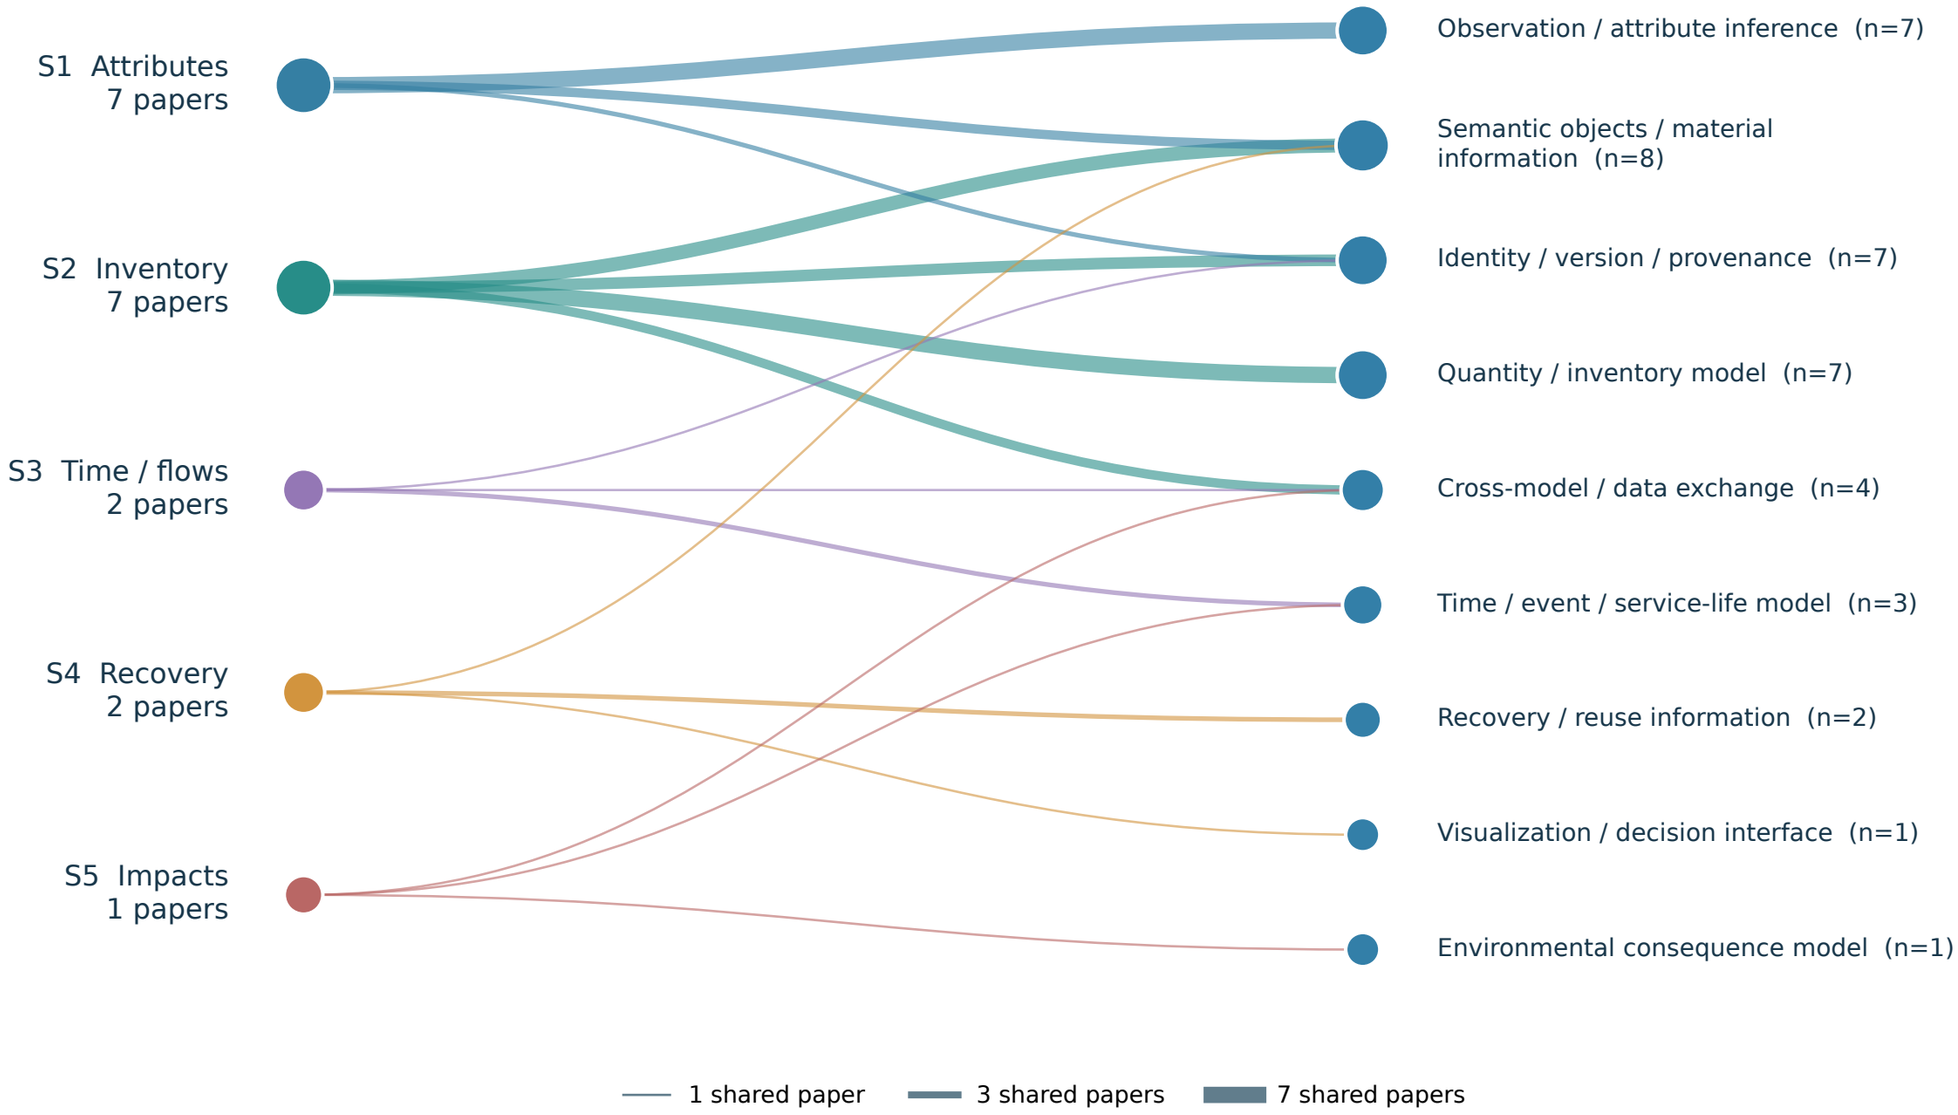

S3 → S4: no assessed article in this selected set; it has no ribbon. This is not proof of absence in the wider literature.

Each assessment has exactly one status. Multiple contexts from one publication remain dependent observations.

Ribbons classify evidence records; they do not show physical material flow or measured transfer of uncertainty.

D02 Which DT/enabling functions occur at each stage?

Weighted network from R-coded stage–function cells: 9 records with S1–S5 functions; 3 adjacent-only records are kept outside this graph.

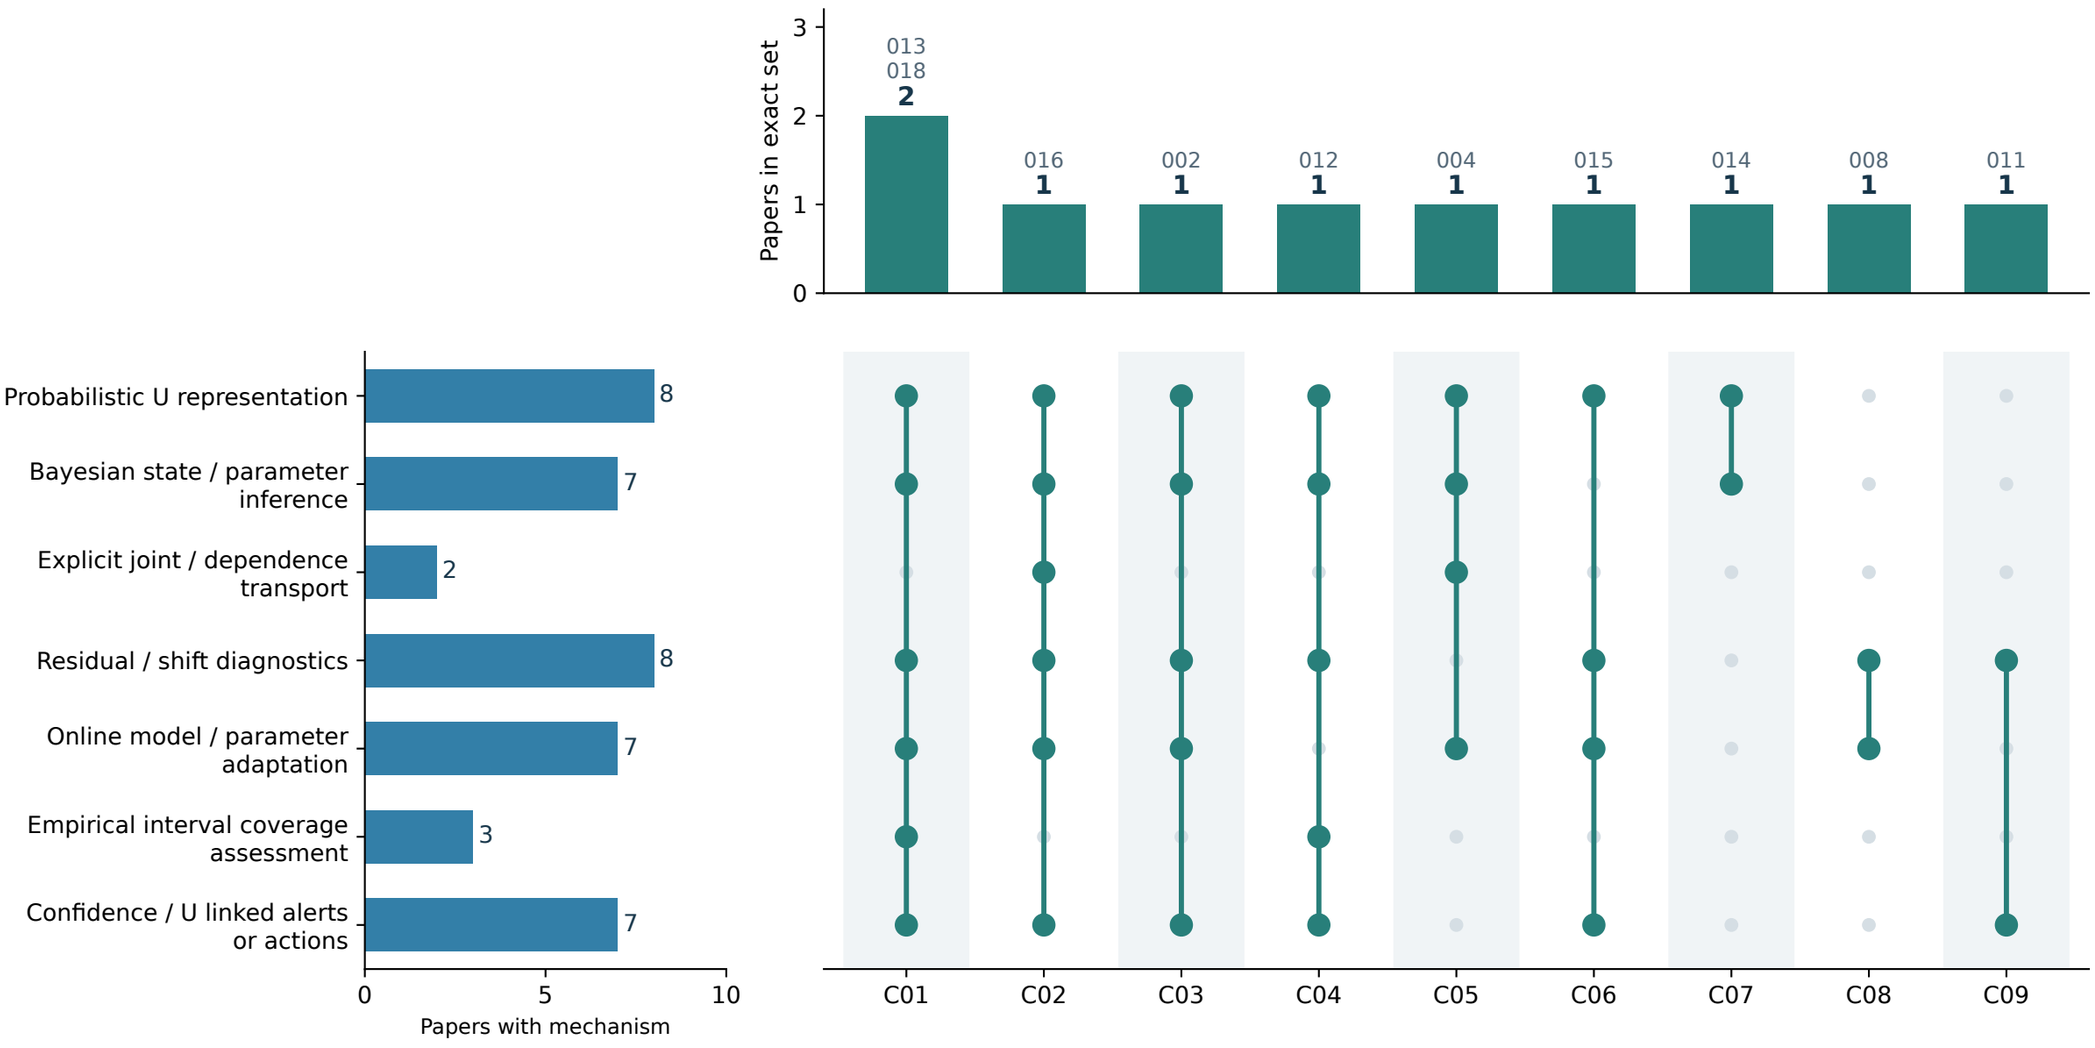

Node area reflects distinct supporting papers. Edge width = papers with that exact stage–function code; all positive edges are shown.

Nodes and edges overlap in membership and must not be summed as unique papers. SVG hover labels and the CSV identify each supporting record.

A connection means the function is coded at that stage. It is not evidence of uncertainty propagation or a working interface between stages.

D03 Which uncertainty configurations are actually recorded?

Exact intersection analysis of 10 non-review records and 7 mechanisms; 9 distinct positive-code configurations.

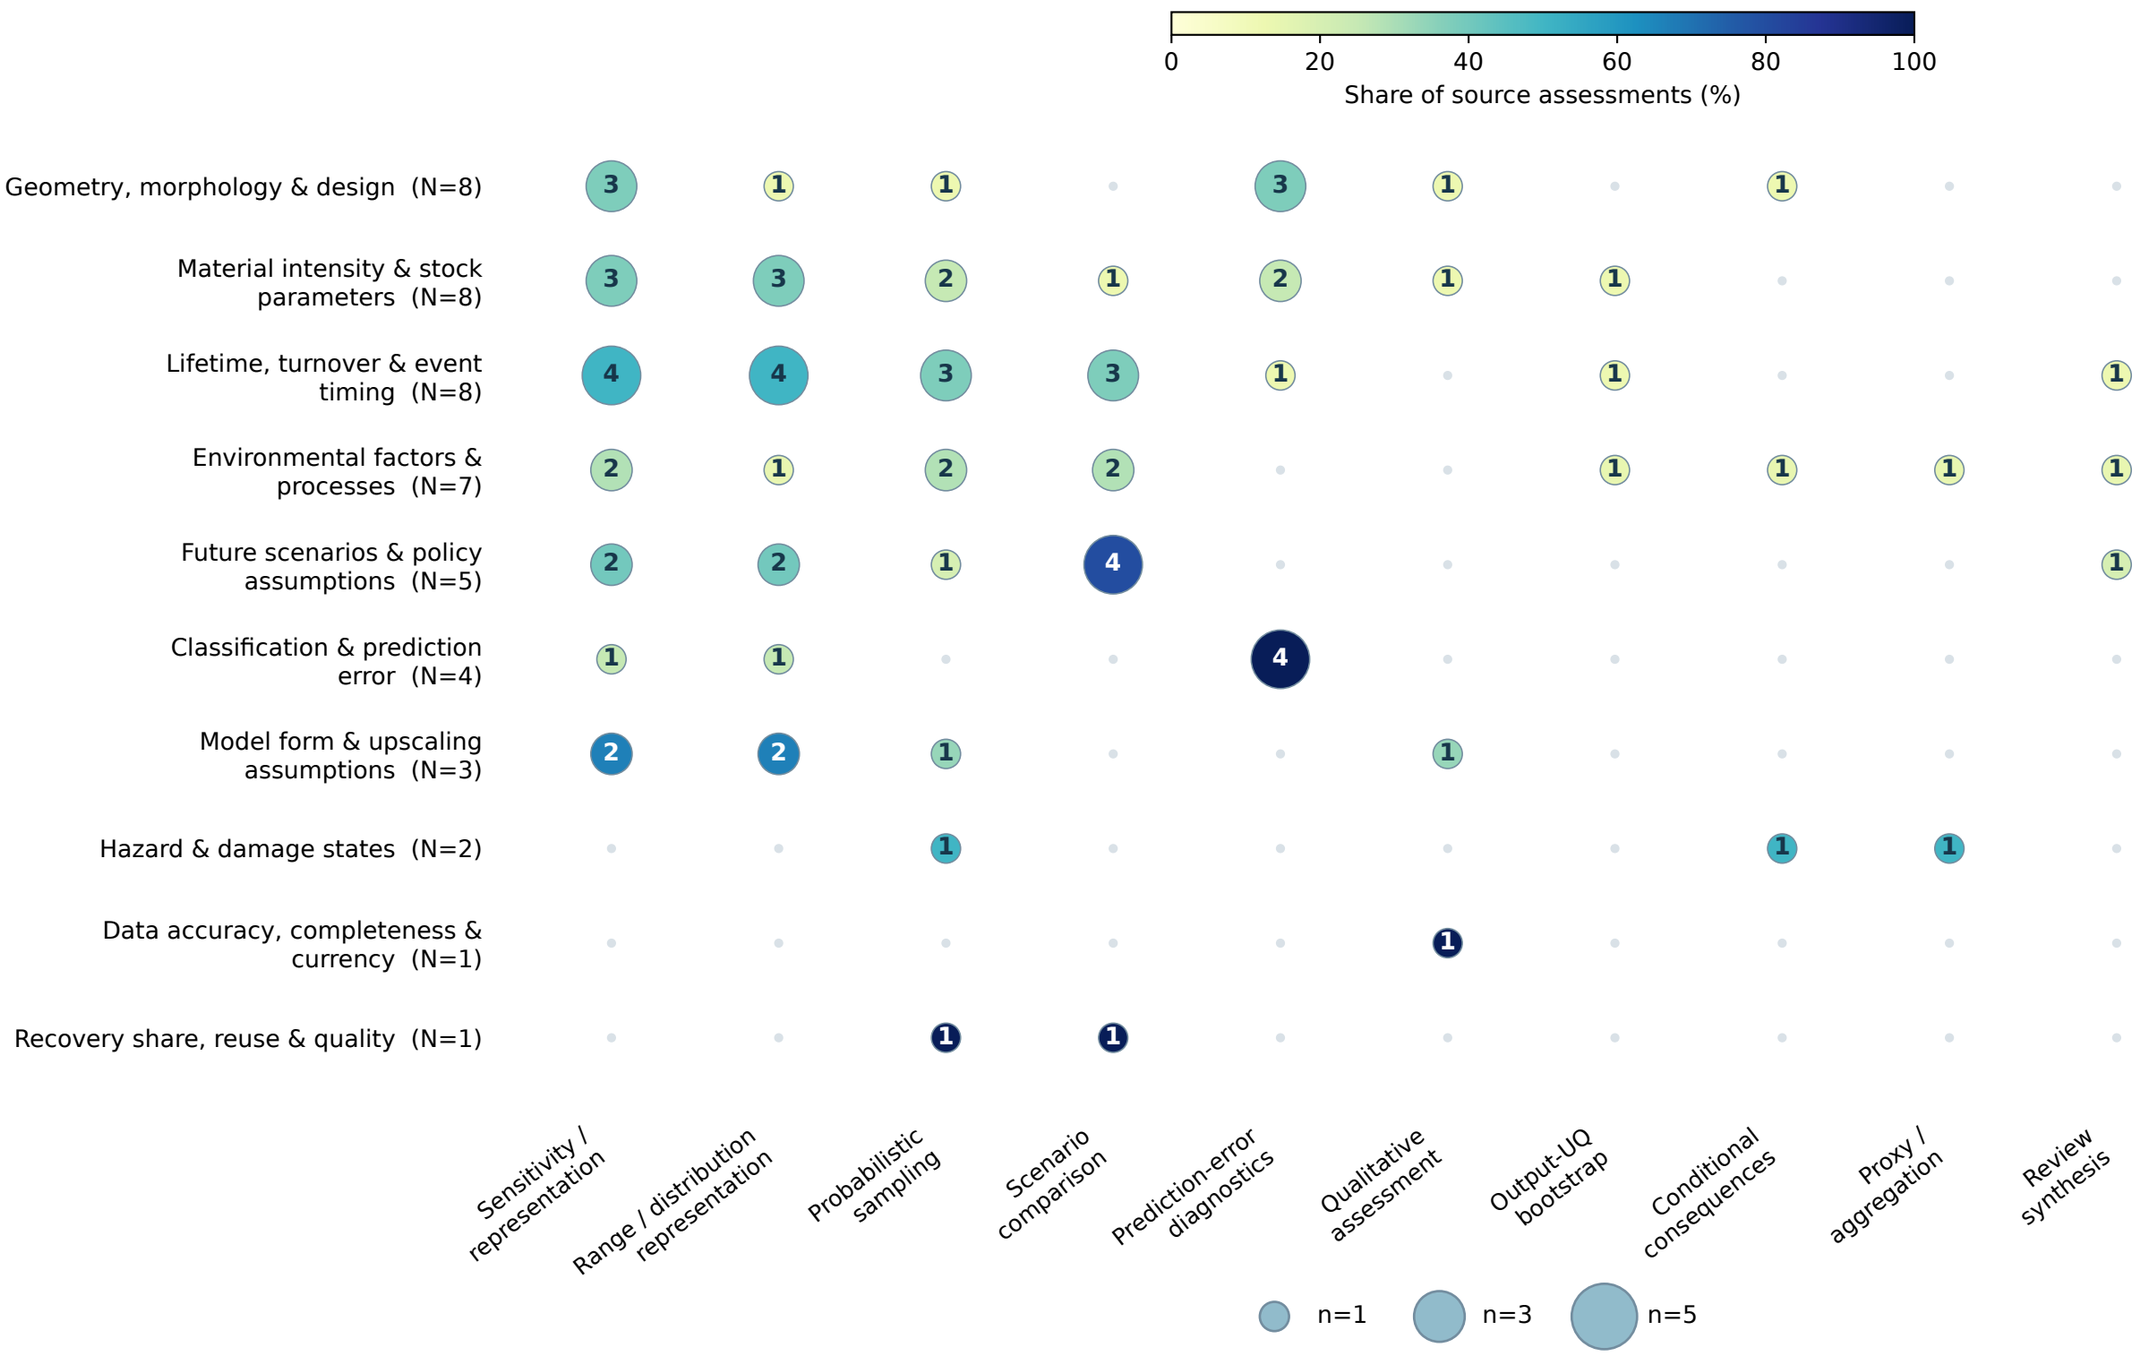

Each column is an observed exact set, not an architecture proposed by the reviewer. Each paper enters exactly one column.

Filled circles indicate R-coded methods. Grey circles mean no positive R code; conceptual support and unrecorded features remain distinct in the source CSV.

Top bars sum to ten records. Three-digit labels identify sources (DTUM prefix omitted). Similar code sets do not establish identical implementations.

D04 Which analysis methods accompany each uncertainty source?

Computed same-paper, same-context associations. Bubble area = assessment count; colour = share of that source’s assessments.

Only codes within the identical publication and boundary are joined. Multiple sources/methods can occur in one assessment; cells are not additive.

The labels describe sources, not automatically epistemic/aleatory categories. A method association does not prove uncertainty transfer.

Zero is no recorded association in this extraction; N is the number of assessed contexts carrying that source. All edges and supporting IDs are exported.
